

Heterogeneous Models of Computation: An Abstract Algebra Approach

EE249 Lecture

Taken from

Roberto Passerone PhD Thesis

Objectives

- ◆ Provide the foundation to represent different semantic domains for the Metropolis metamodel
- ◆ Study the problem of *heterogeneous interaction*
- ◆ Formalize concepts such as abstraction and refinement

An Example of Interaction

- ◆ Combine a synchronous model with a dataflow model
- ◆ Synchronous model
 - ◆ Total order of event
- ◆ Data flow model
 - ◆ Partial order of events
- ◆ Discrete Time model
 - ◆ Metric order of events

An Example of Heterogeneous Interaction

- ◆ The interaction is derived from a **common refinement** of the heterogeneous models
- ◆ The resulting interaction depends on the **particular refinements employed**
- ◆ Our objective is to derive the **consequences** of the interaction at the **higher levels of abstraction**

Data Flow Model

- ◆ Assume signals take values from a set V
- ◆ Each signal is a sequence from V (an element of V^*)
- ◆ Let A be the set of signals
- ◆ One behavior is a function
 - ◆ $f : A \rightarrow V^*$
- ◆ A data-flow agent is a set of those behaviors

Synchronous Model

- ◆ Signals are again sequences from V (elements of V^*)
- ... But are synchronized
- ◆ One element of the sequence is $g : A \rightarrow V$
- ◆ One behavior is a sequence of those functions
 - ◆ $\langle g_i \rangle \in (A \rightarrow V)^*$
- ◆ A synchronous agent is a set of those sequences

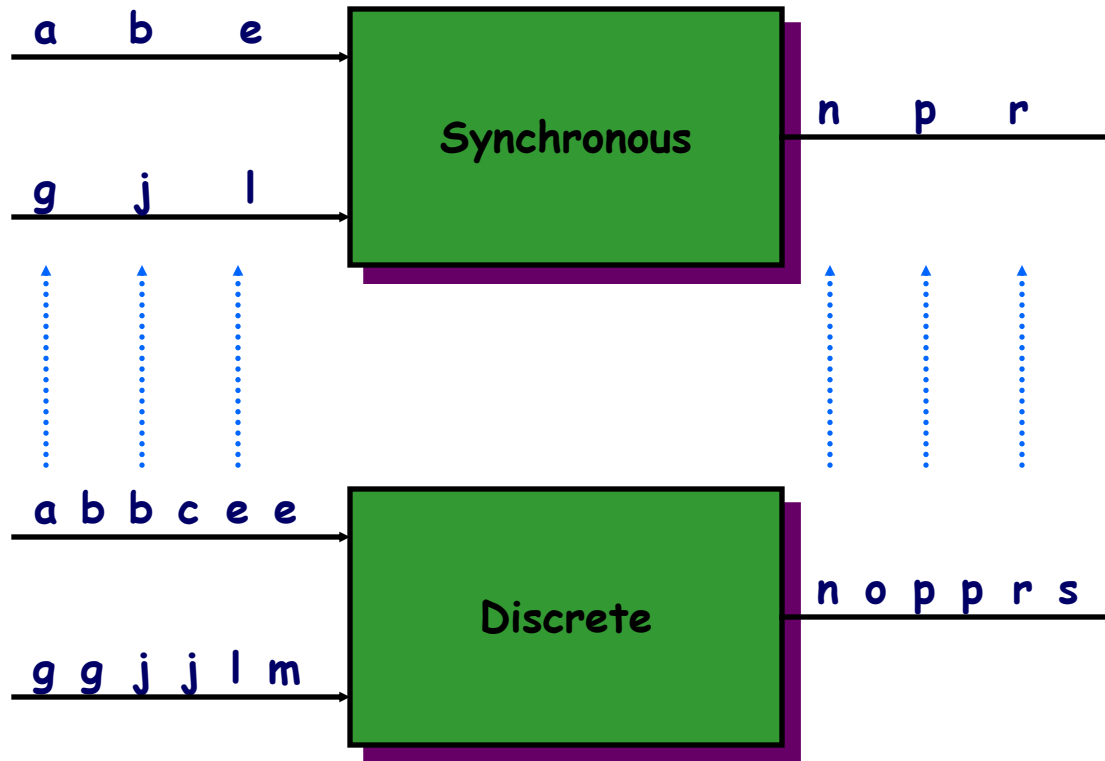

Discrete Time Model

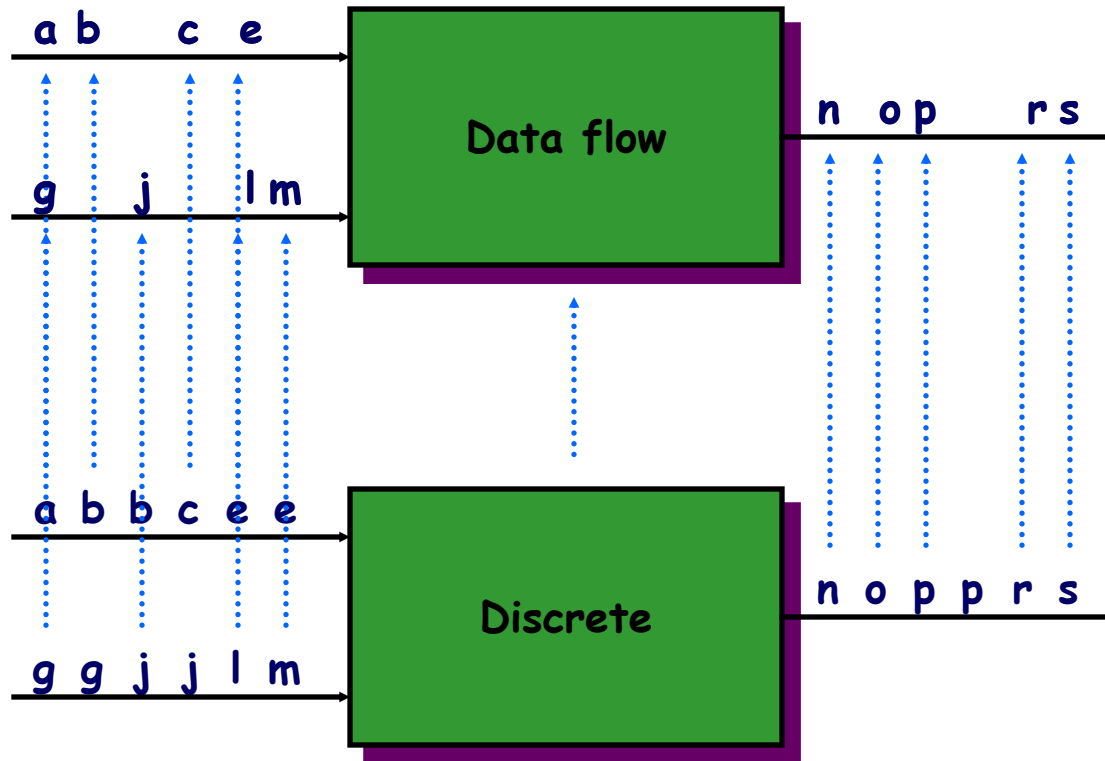

- ◆ Assume time is represented by the positive integers N
- ◆ Then define a behavior
 - ◆ $h: N \rightarrow (A \rightarrow V)$
- ◆ A discrete time agent is a set of those functions

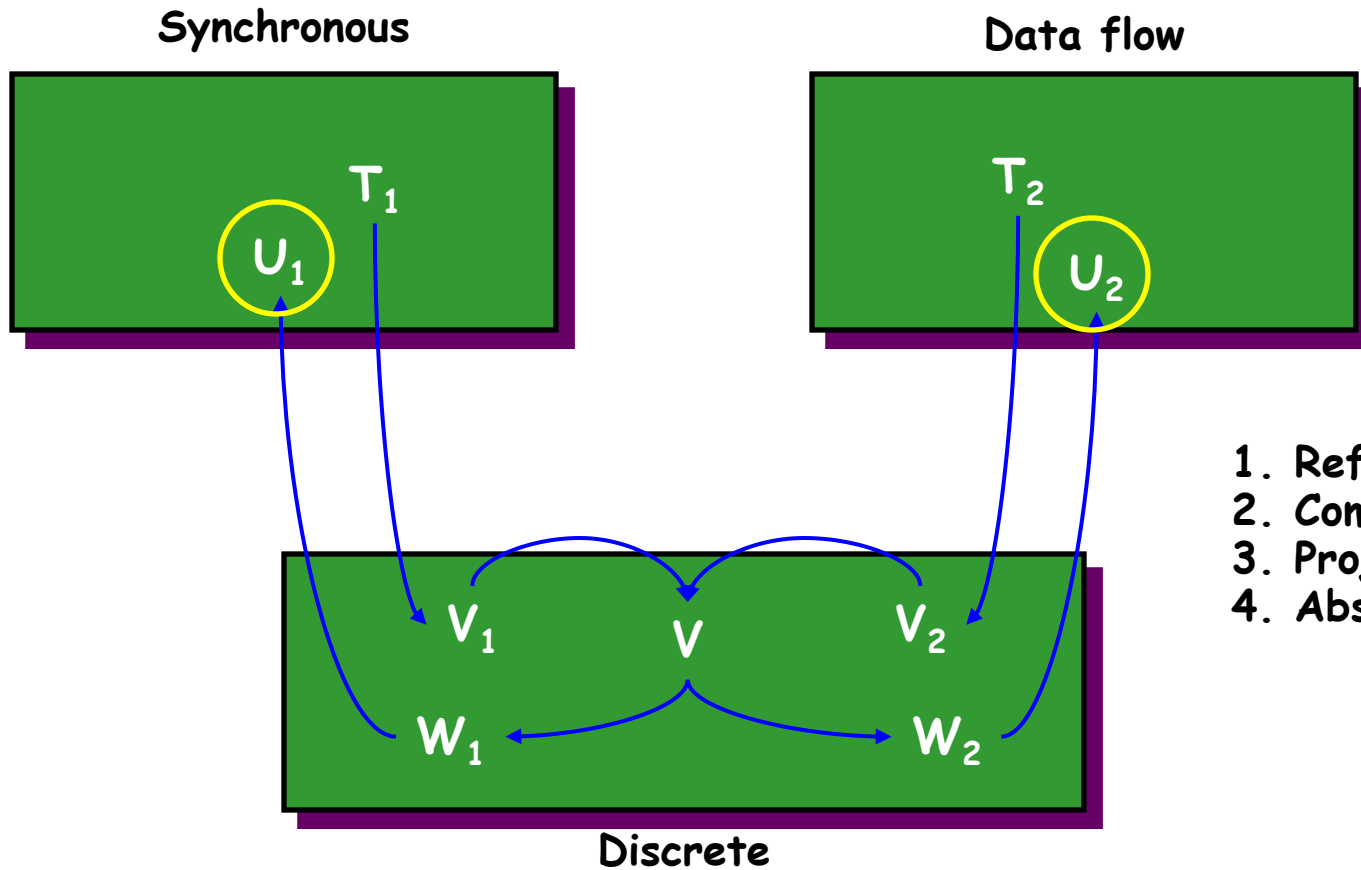

Discrete to Synchronous Abstraction

Discrete to Data Flow Abstraction

Interaction Propagation

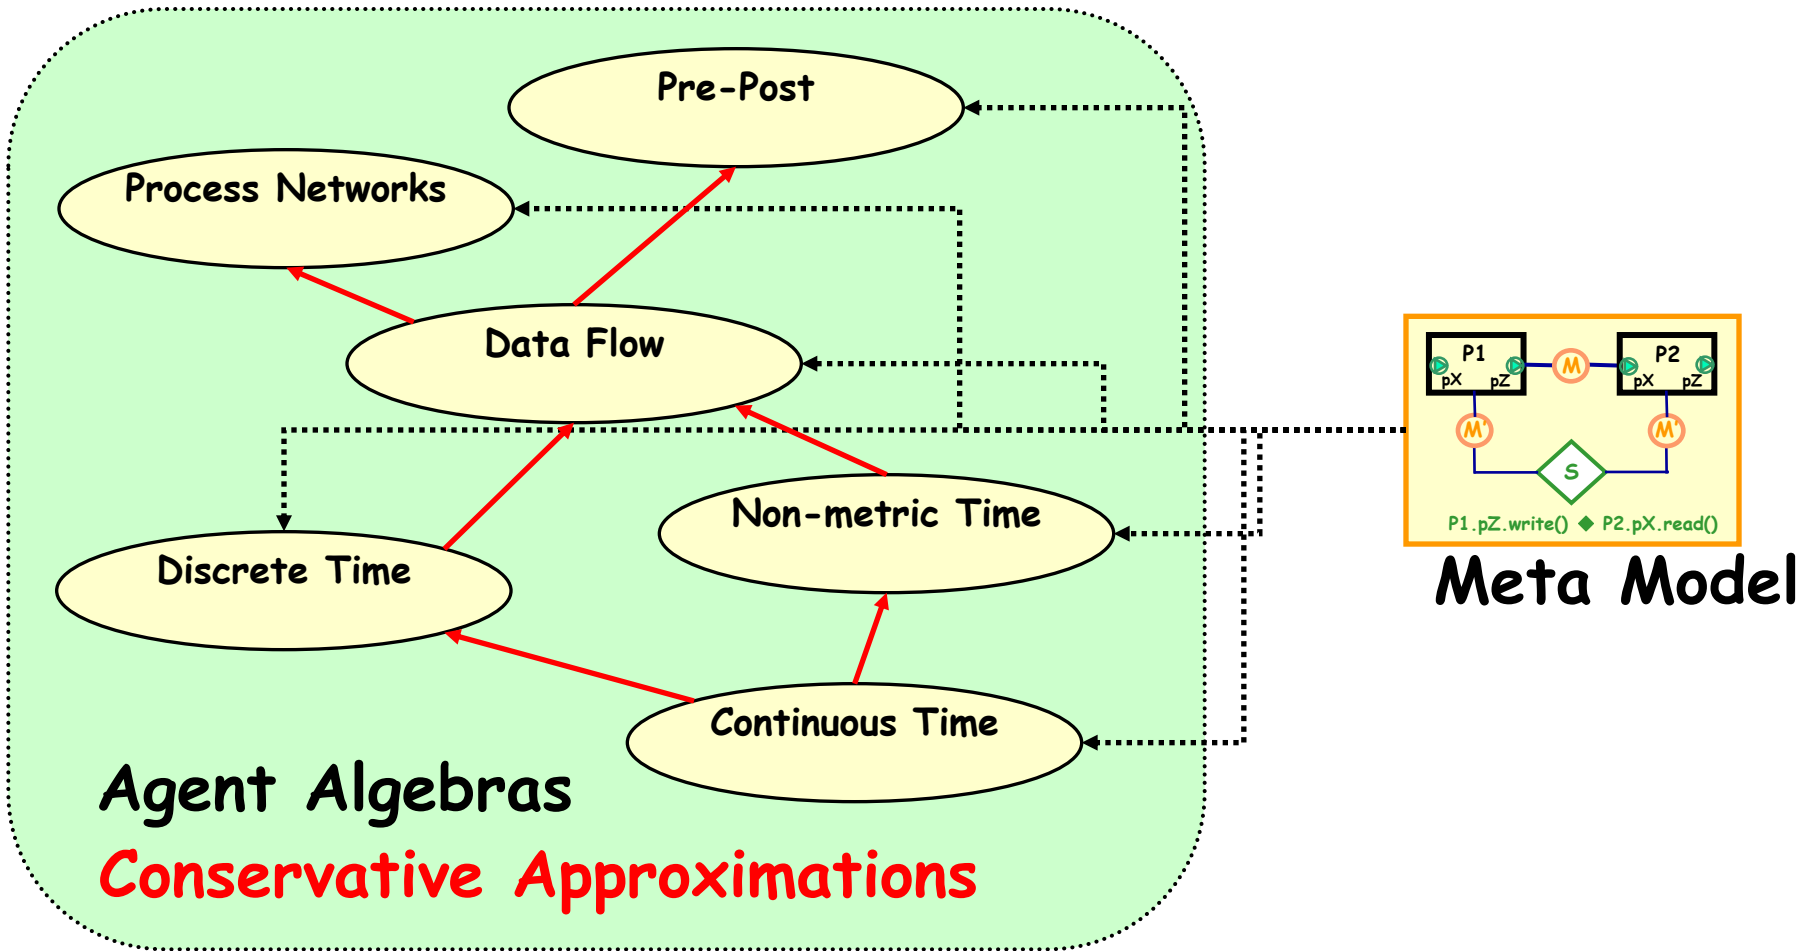

1. Refinement
2. Composition
3. Projection
4. Abstraction

Objectives

- ◆ Provide a semantic foundations for integrating different models of computation
 - ◆ Independent of the design language
- ◆ Maximize flexibility for using different levels of abstraction
 - ◆ For different parts of the design
 - ◆ At different stages of the design process
 - ◆ For different kinds of analysis
- ◆ Support many forms of abstraction
 - ◆ Model of computation (model of time, synchronization, etc.)
 - ◆ Scoping
 - ◆ Structure (hierarchy)

Overview

Domain of agents with operations: projection, renaming and composition

Scope

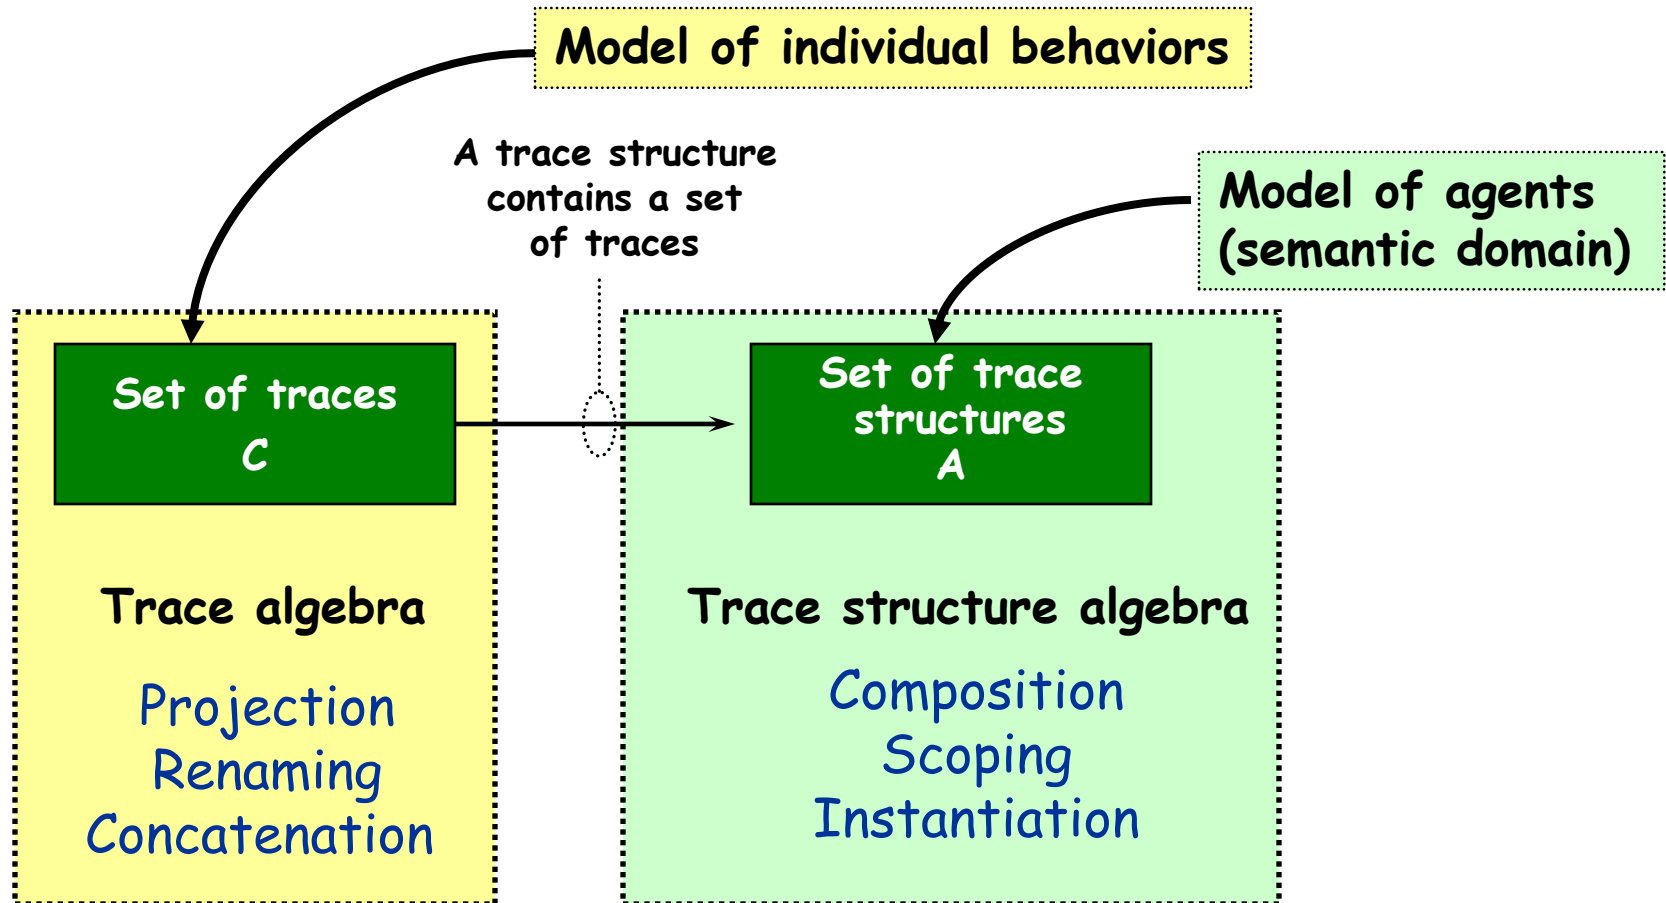

- ◆ Concentrate on
 - ◆ Natural semantic domains (sets of agents)
 - ◆ Relations and functions over semantic domains
 - ◆ Relationships between semantic domains and their relations and functions
- ◆ Defer worrying about specific abstract syntaxes and semantic functions
 - ◆ Convenient for manual, formal reasoning
 - ◆ De-emphasizing executable and finitely-representable models (for now)

Agents and Behaviors

- ◆ For each model of computation we always distinguish between
 - ◆ the domain of individual behaviors
 - ◆ the domain of agents
- ◆ For different models of computation individual behaviors can be very different mathematical objects
 - ◆ We always call these objects **traces**
 - ◆ The nature of the elements of the carrier is irrelevant!
- ◆ An agent is primarily a set P of traces
 - ◆ We call them **trace structures**
 - ◆ Also includes the signature: $T = (\gamma, P)$

Trace and Trace Structure Algebras

Essential Elements

- ◆ **Must be able to name elements of the model**
 - ◆ Variables, actions, signals, states
 - ◆ We do not distinguish among them and refer to them collectively as a set of signals W
- ◆ **Each agent has an alphabet and a signature**
 - ◆ Alphabet: $A \subseteq W$
 - ◆ Signature: $\gamma = A, \gamma = (I, O), \text{ etc.}$
- ◆ **The operations on traces and trace structures must satisfy certain axioms**
 - ◆ The axioms formalize the intuitive meaning of the operations
 - ◆ They also provide hypothesis used in proving theorems
 - ◆ Trade-off between generality and structure

Metric Time Traces

$$\gamma = (V_R, V_N, M_I, M_O)$$

$$x = (\gamma, \delta, f)$$

$$f(v) = [0, \delta] \rightarrow R$$

$$f(n) = [0, \delta] \rightarrow N$$

$$f(a) = [0, \delta] \rightarrow \{0, 1\}$$

◆ Model time as a metric space

- ◆ Can talk about the difference in time between points in the behavior in quantitative terms
- ◆ Able to specify timing constraints in quantitative terms

◆ Able to represent continuous as well as discrete behavior

◆ Projection and renaming easily defined on the functions

Metric Time Model: Traces

- ◆ A trace x models one execution of a hybrid system:
- ◆ Signature $\gamma = ($
 - V_R : real valued var's,
 - V_N : integer valued var's,
 - M_I : input actions,
 - M_O : output actions)
- ◆ The alphabet A of x is the union of the components of γ
- ◆ δ is a non-negative real number
 - Length (in time) of x
 - Can be infinity

- ◆ f gives values as a function of time:

$$f: V_R \dashrightarrow [0, \delta] \dashrightarrow \mathbb{R},$$

$$f: V_N \dashrightarrow [0, \delta] \dashrightarrow \mathbb{N},$$

$$f: M_I \dashrightarrow [0, \delta] \dashrightarrow \{0, 1\},$$

$$f: M_O \dashrightarrow [0, \delta] \dashrightarrow \{0, 1\}.$$

Metric Time Model: Operations on Traces

◆ Let $x' = \text{proj}(B)(x)$

- ◆ represents scoping
- ◆ B is a subset of A
- ◆ γ' and f' are restricted to variables and actions in B
- ◆ $\delta' = \delta$

◆ Let $x' = \text{rename}(r)(x)$

- ◆ represents instantiation
- ◆ r is a one-to-one function with domain A
- ◆ variables and actions in γ' and f' are renamed by r
- ◆ $\delta' = \delta$

◆ Let $x'' = x \cdot x'$

(concatenation)

- ◆ represents sequential composition
- ◆ $\gamma' = \gamma$, δ is finite, and end of x matches beginning of x'
- ◆ $\gamma'' = \gamma$
- ◆ $\delta'' = \delta + \delta'$
- ◆ $f''(v, t)$ is equal to
 $f(v, t)$ for $t \leq \delta$
 $f'(v, t - \delta)$ for $t \geq \delta$

Metric Time Model: Trace Structures

- ◆ A trace structure $T = (\gamma, P)$ models a process or an agent of a hybrid system
 - ◆ P is a set of traces with signature γ

Traits:

- ◆ T refines T' if $P \subseteq P'$
- ◆ Natural model for physical components (such as those described with differential equations, possibly with discrete control variables)
- ◆ Too detailed for many other aspects of embedded systems
- ◆ Not a finite representation
 - ◆ Finite representations, synthesis and verifications algorithms are clearly important, but not a focus of this class
- ◆ Trace structures constructed the same way for any trace algebra

Metric Time Model: Operations on Trace Structures

◆ Let $T' = \text{proj}(B)(T)$

- ◆ B is a subset of A
- ◆ γ' is restricted to variables and actions in B
- ◆ $P' = \text{proj}(B)(P)$

◆ Let $T' = \text{rename}(r)(T)$

- ◆ r is a one-to-one function with domain A
- ◆ variables and actions in γ' are renamed by r
- ◆ $P' = \text{rename}(r)(P)$

◆ Let $T'' = T \parallel T'$ (par. comp.)

- ◆ γ'' combines γ and γ'
- ◆ P'' maximal set s.t.
 $P = \text{proj}(A)(P'')$
 $P' = \text{proj}(A')(P'')$

◆ Let $x'' = x \cdot x'$ (seq. comp.)

- ◆ $\gamma'' = \gamma$
- ◆ $P'' = P \cdot P'$ (roughly)

Non-metric Time Traces

$$\gamma = (V_R, V_N, M_I, M_O)$$

$$x = (\gamma, L)$$

$$m(t) = V_R \rightarrow R$$

$$V_N \rightarrow N$$

$$M \rightarrow \{0, 1\}$$

◆ Model time as a non-metric space

- Can only talk about precedence in time (including dense time)

◆ Based on Totally Ordered Multi-Sets

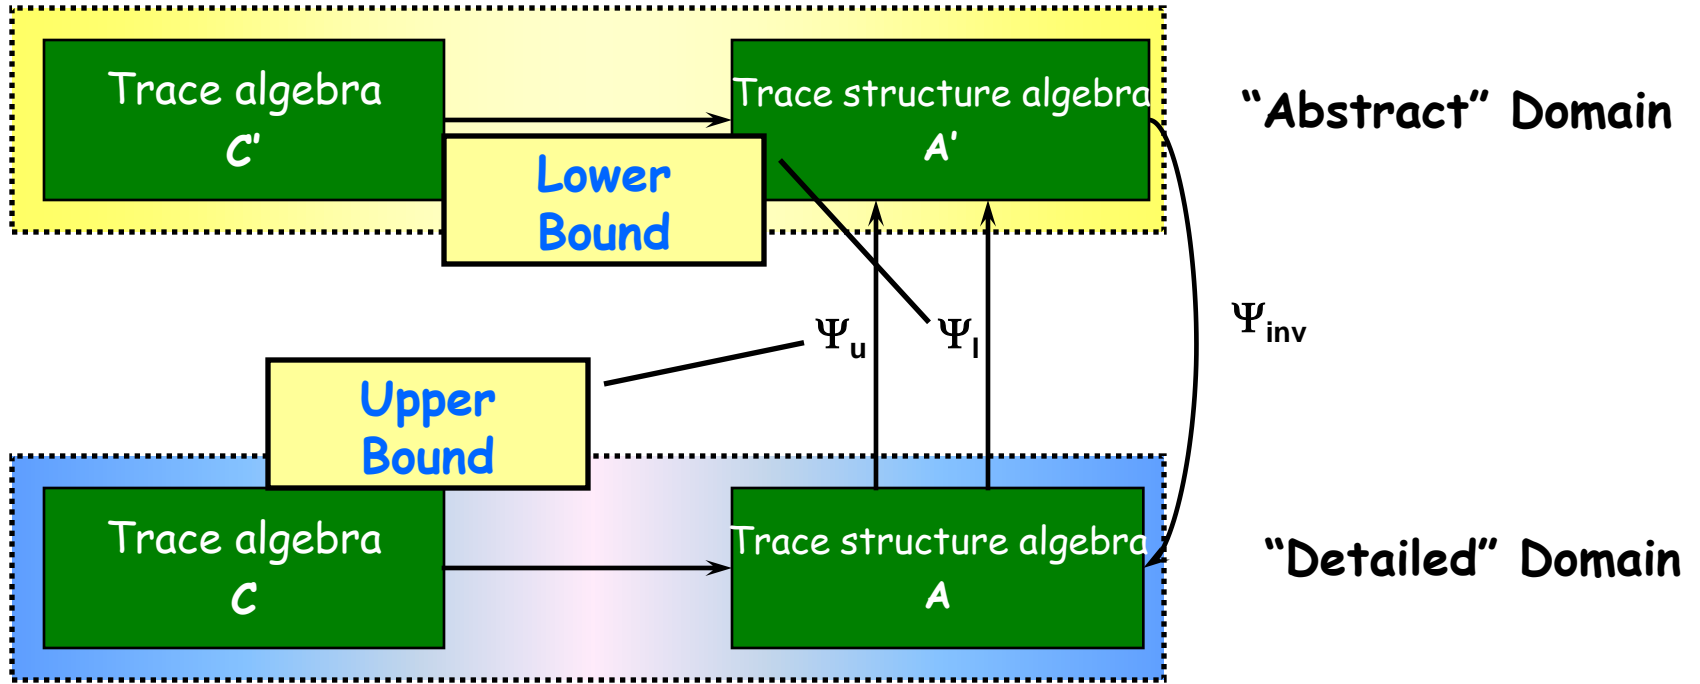

- Totally ordered vertex set V
- Labeling function μ from the vertex set V to a set of actions Σ
- We do not distinguish isomorphic vertex sets

Relationships between Semantic Domains

- ◆ Each semantic domain has a refinement order
 - ◆ Based on trace containment
 - ◆ $T_1 \subseteq T_2$ means T_1 is a refinement of T_2
 - ◆ Guiding intuition: $T_1 \subseteq T_2$ means T_1 can be substituted for T_2
- ◆ Abstraction mapping
 - ◆ If a function H between semantic domains is monotonic, detailed implies abstract: If $T_1 \subseteq T_2$ then $H(T_1) \subseteq H(T_2)$
 - ◆ Analogy for real numbers r and s : If $r \leq s$ then $\lfloor r \rfloor \leq \lfloor s \rfloor$
- ◆ Conservative approximations
 - ◆ A pair of functions $\Psi = (\Psi_l, \Psi_u)$ is a *conservative approximation* if $\Psi_u(T_1) \subseteq \Psi_l(T_2)$ implies $T_1 \subseteq T_2$
 - ◆ Analogy: $\lceil r \rceil \leq \lfloor s \rfloor$ implies $r \leq s$
 - ◆ Abstract implies detailed

Trace and Trace Structure Algebras

Deriving Conservative Approximations

Homomorphism: mapping that commutes with the operations of projection, renaming and concatenation on traces

Homomorphism

◆ From metric to non-metric

- ◆ Must define a notion of event in the metric model
- ◆ Must define how to construct the corresponding vertex set

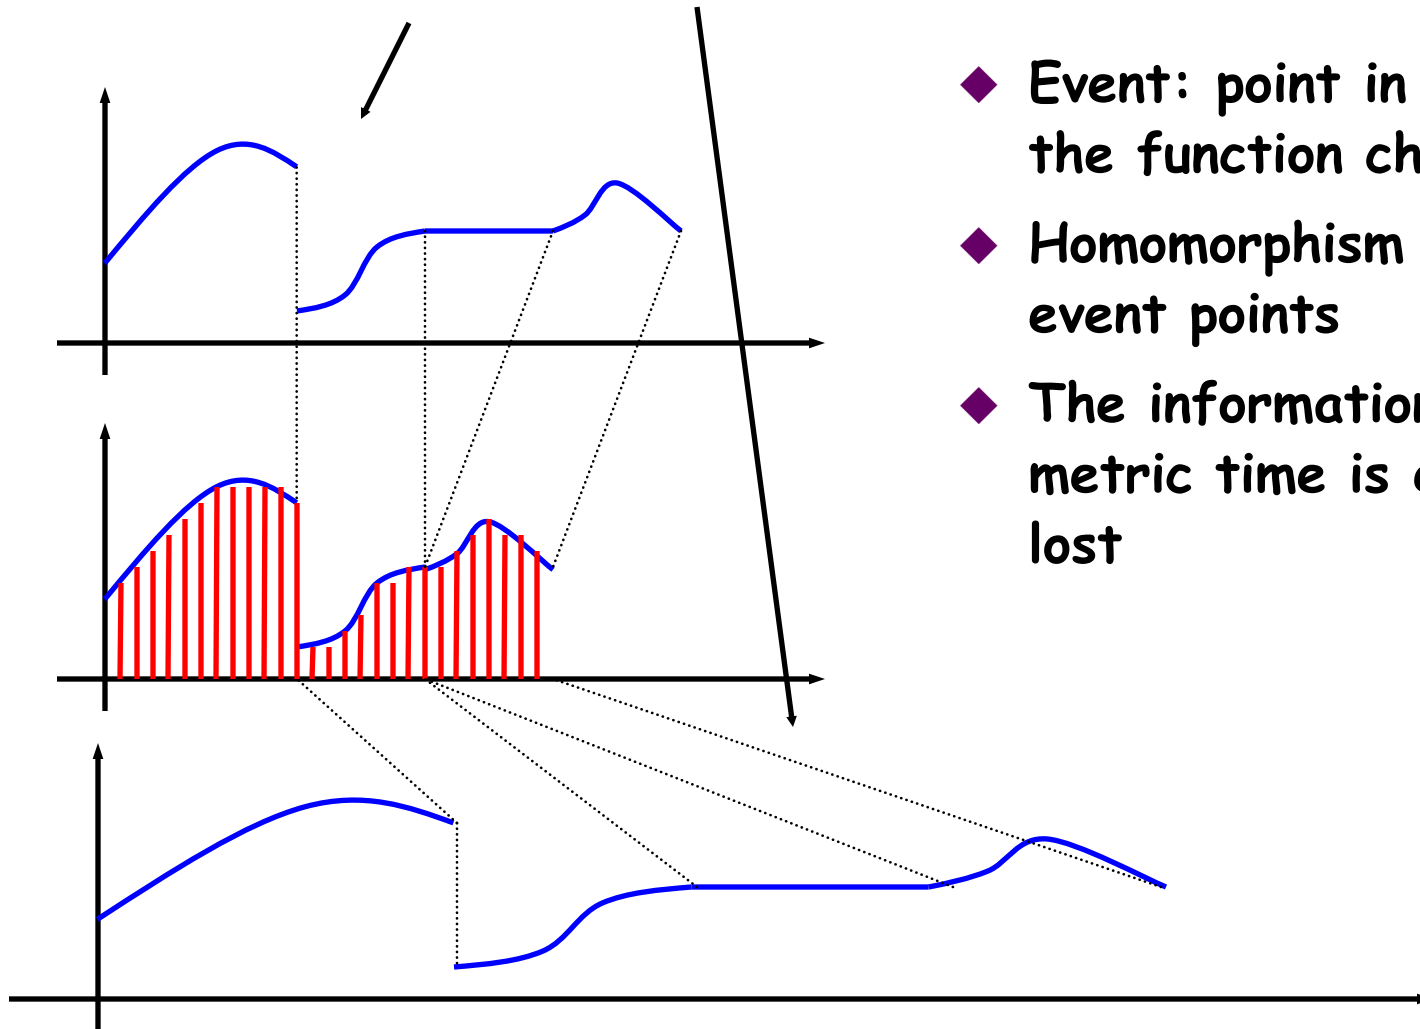

◆ From non-metric to pre-post

- ◆ Simply remove the intermediate steps and keep only the end-points

Metric to Non-Metric Traces

Equivalent traces

- ◆ Event: point in time where the function changes value
- ◆ Homomorphism discards non-event points
- ◆ The information about metric time is effectively lost

From Metric to Non-metric Time

- f is stable at t_0 if there is $\varepsilon > 0$ such that f is constant on $[t_0 - \varepsilon, t_0]$
- f has an event at t_0 if it is not stable
- Vertex Set $V = \{t_0 \mid f \text{ has an event at } t_0\}$

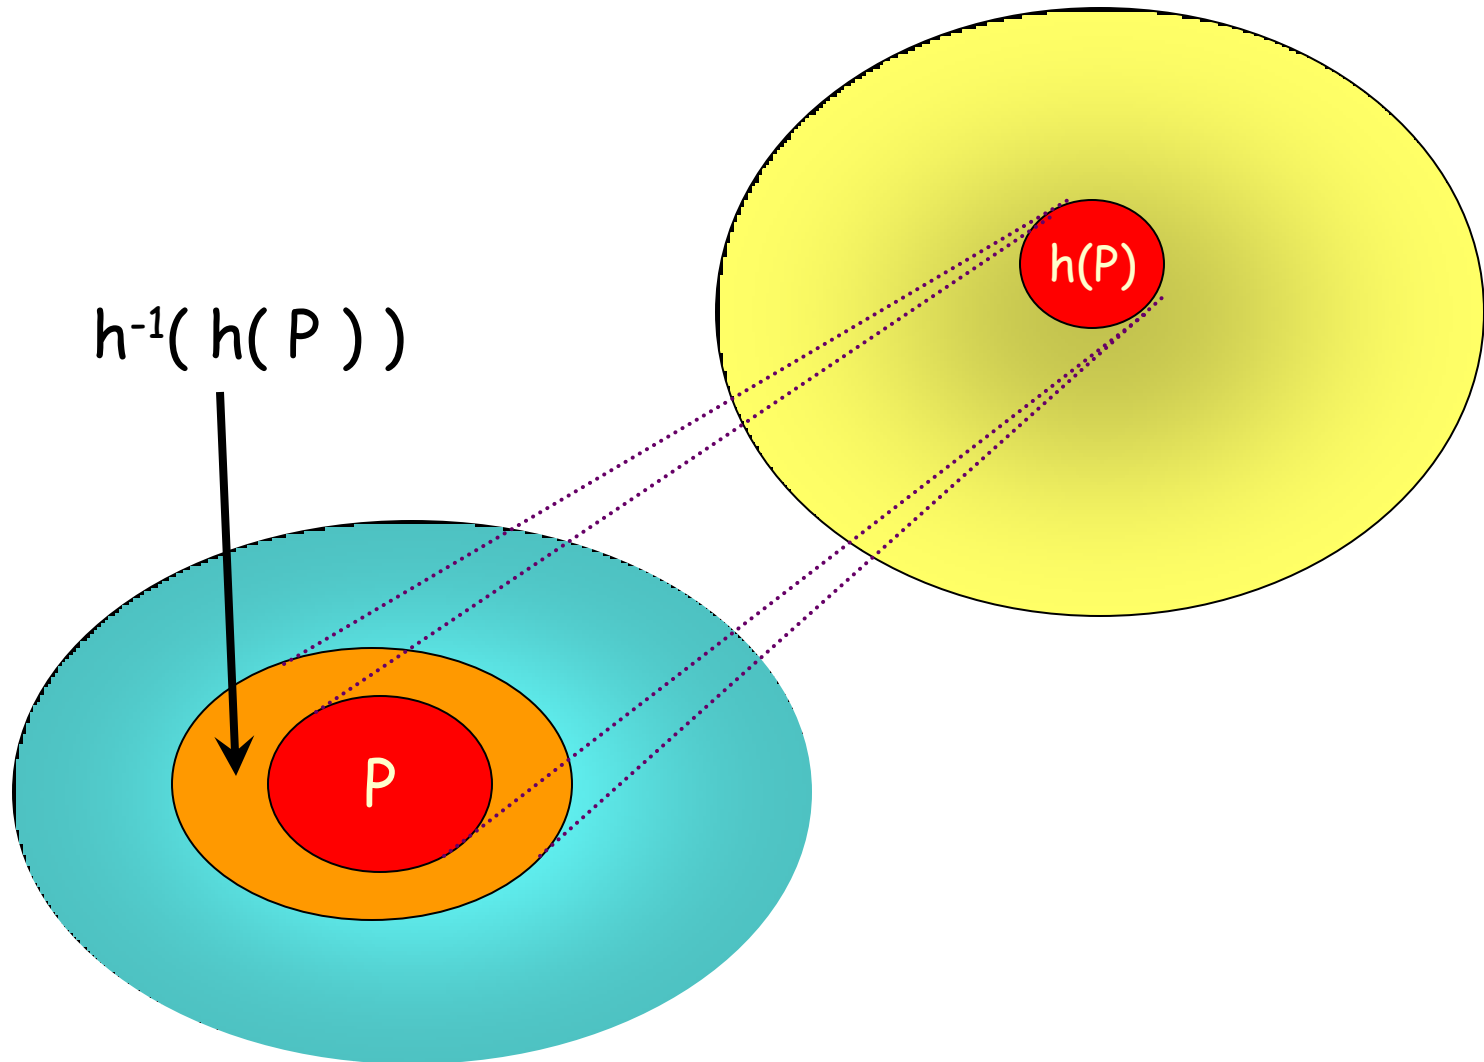

Building the Upper Bound

- ◆ Let P be a set of traces, and consider the natural extension to sets $h(P)$ of h
- ◆ Clearly $P \subseteq h^{-1}(h(P))$
 - ◆ Because h is many-to-one
 - ◆ This indeed is an upper bound!
 - ◆ Equality holds if h is one-to-one
- ◆ Hence define
 - ◆ $\Psi_u(T) = (\gamma, h(P))$

Building the Upper Bound

Building the Lower Bound

- ◆ We want $P \supseteq h^{-1}(\text{lb of } P)$
- ◆ If x is not in P , then $h(x)$ should not be in the lower bound of P
- ◆ Hence define
 - $\Psi_1(T) = h(P) - h(B_c(A) - P)$
- ◆ There is a tighter lower bound

Building the Lower Bound

Conservative Approximations: Inverses

◆ Apply Ψ_u

◆ Apply Ψ_l

◆ Consider \mathcal{T} such that

$$\Psi_u(\mathcal{T}) = \Psi_l(\mathcal{T}) = \mathcal{T}'$$

Conservative Approximations: Inverses

- ◆ Apply Ψ_u
- ◆ Apply Ψ_l
- ◆ Consider \mathcal{T} such that
$$\Psi_u(\mathcal{T}) = \Psi_l(\mathcal{T}) = \mathcal{T}'$$
- ◆ Then $\Psi_{inv}(\mathcal{T}') = \mathcal{T}$

Conservative Approximations: Inverses

Ψ_{inv} \longrightarrow

- ◆ Apply Ψ_u
- ◆ Apply Ψ_l
- ◆ Consider \mathcal{T} such that
$$\Psi_u(\mathcal{T}) = \Psi_l(\mathcal{T}) = \mathcal{T}'$$
- ◆ Then $\Psi_{inv}(\mathcal{T}') = \mathcal{T}$
- ◆ Can be used to embed high-level model in low level

Combining MoCs

Want to compose T_1 and T_2 from different trace structure algebras

- ◆ Construct a third, more detailed trace algebra, with homomorphisms to the other two
- ◆ Construct a third trace structure algebra
- ◆ Construct cons. approximations and their inverses
- ◆ Map T_1 and T_2 to T_1' and T_2' in the third trace structure algebra
- ◆ Compose T_1' and T_2'

Conclusions

- ◆ Semantic foundations for the Metropolis meta-model
- ◆ All models of computation of importance “reside” in a unified framework
 - ◆ They may be better understood and optimized
- ◆ Trace Algebra used as the underlying mathematical machinery
 - ◆ Showed how to formalize a semantic domain for several models of computation
- ◆ Conservative approximations and their inverses used to relate different models
