## Lecture 6: Modeling Modal Behavior, Part I

Roadmap for course (until spring break):  
**Modeling, Analysis, and Control**

*What goes into “CAD tools” for embedded systems?*

### **Modeling**

Feb 11, 13: “Pure” Modal Modeling (finite-state machines)

Feb 20: Concurrency

Feb 25, 27: Hybrid Systems (modeling discrete +  
continuous behavior)

EECS 124, UC Berkeley: 2

## Roadmap for course (until spring break)

### Analysis and Control

*Analysis: Does my model satisfy its specification?*

Mar 3, 5: Techniques to simulate discrete/continuous/hybrid models

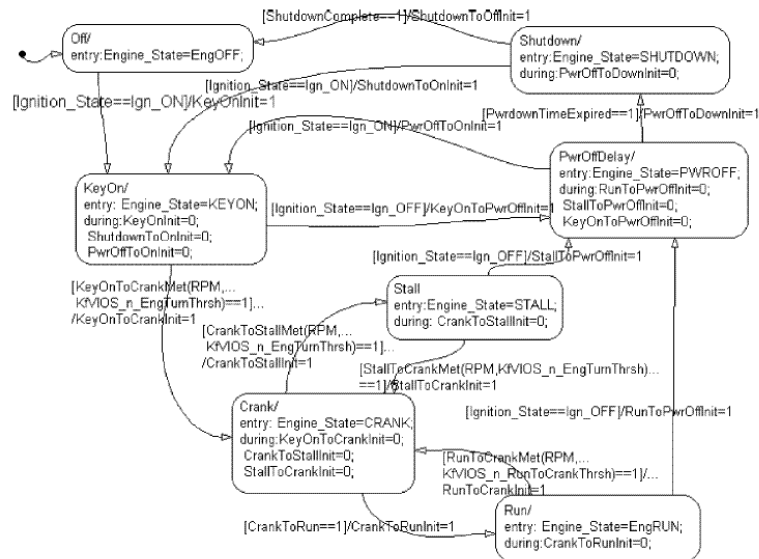

Mar 10, 12: Exhaustive state-space exploration techniques, reachability analysis, model checking

*Control: Synthesizing a strategy to achieve a goal*

Mar 17, 19: Controller synthesis for hybrid systems

EECS 124, UC Berkeley: 3

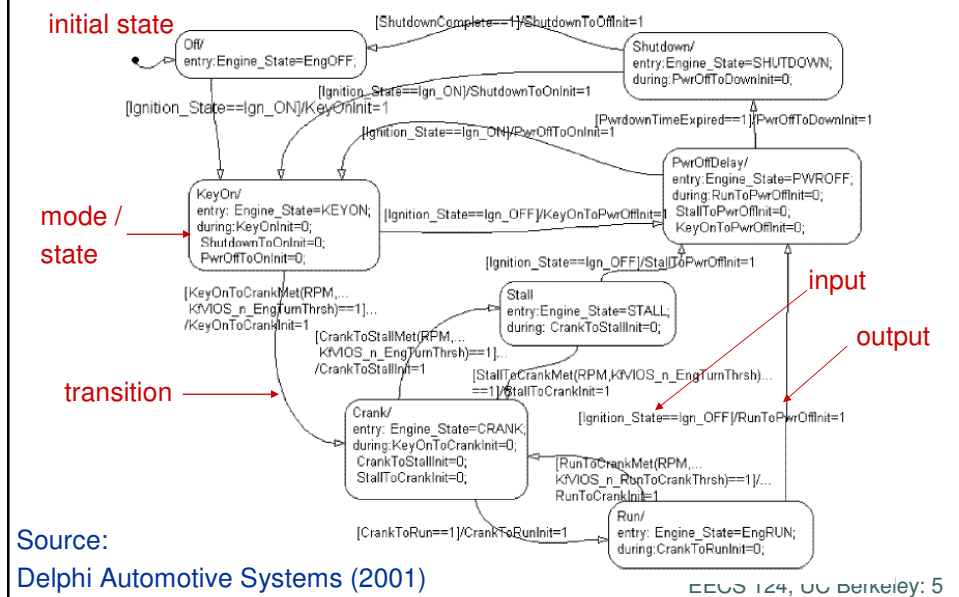

## Modal Model (Finite-State Machine) for Engine Control

Source:  
Delphi Automotive Systems (2001)

EECS 124, UC Berkeley: 4

## Elements of a Modal Model (FSM)

## Topic: Modeling with Finite-State Machines (FSMs)

Suppose that our only modeling formalism is the Finite-State Machine

Four questions:

- How to represent the system for:
  - Mathematical analysis
  - So that a computer program can manipulate it
- How to model its environment?
- How to represent what the system **MUST** do – its specification?
- How to check whether the system satisfies its specification in its operating environment?

## Example: Discretized iRobot Hill Climber

EECS 124, UC Berkeley: 7

## Main Concepts in this Lecture

Q1: System representation

- Finite-state machine – syntax and semantics
- Behavior/trace on infinite inputs

Q2 & 3: Environment modeling/specification

- Non-determinism
  - Abstraction in modeling

Q4: Comparing state machines

- Simulation, bisimulation, trace equivalence and trace containment
  - How do we know whether implementation does what the specification states?

EECS 124, UC Berkeley: 8

## State Machines: Formal Definition

A state machine is a tuple:

(States, Inputs, Outputs, update, initialState)

where

States = set of states/modes of the system

Inputs = set of input symbols

Outputs = set of output symbols

update: States  $\times$  Inputs  $\rightarrow$  States  $\times$  Outputs

- called “transition function” or “update function”

initialState = the starting state/mode of the system

- denoted by incoming arrow or special “init” label

EECS 124, UC Berkeley: 9

## Finite State Machines

The definition on the previous slide is general – the state machine could have *infinitely many* states

We will restrict ourselves to a **finite** set of states, in this and the next lecture

EECS 124, UC Berkeley: 10

## FSM Steps and Signals

Each time a transition occurs, the FSM takes a **step**  
(note: time need not advance)

StepNumbers =  $\{0, 1, 2, \dots\} = \mathbb{N}$

A **signal** is a function mapping  $\mathbb{N}$  to symbols

- Input, output, and control (state-holding) signals
- We will restrict attention to “pure” signals
  - Signal models presence/absence of an event

An **input/output symbol** is an element of  $\{\text{present}, \text{absent}\}^n$  (assuming  $n$  input/output signals)

EECS 124, UC Berkeley: 11

## Example: Discretized iRobot Hill Climber

EECS 124, UC Berkeley: 12

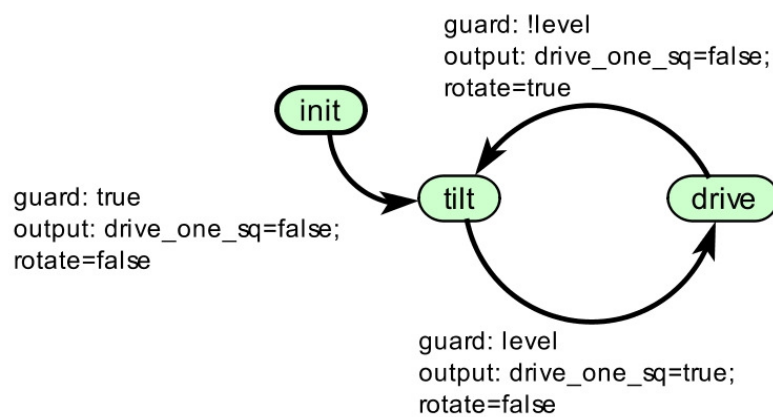

## The Input/Output Interface of the iRobot Controller

<u>Signal that is present</u>	<u>What it means</u>
level	Robot is facing the right way up/down hill
rotate	Robot rotates by 45° clockwise
drive_one_sq	Robot drives to neighboring square

EECS 124, UC Berkeley: 13

## FSM Controller for iRobot

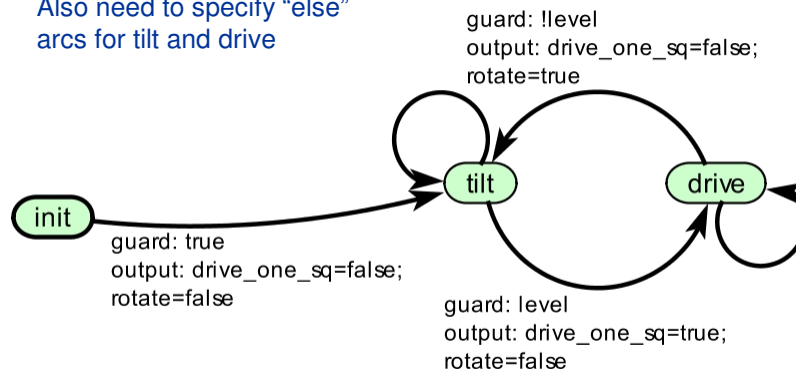

States = {init, tilt, drive}    Inputs = ?    Outputs = ?  
 update = ?    Any transitions missing?

EECS 124, UC Berkeley: 14

## FSM Controller for iRobot (version 2)

Also need to specify "else" arcs for tilt and drive

Will this robot always drive uphill?  
(assume that it starts facing uphill)

EECS 124, UC Berkeley: 15

## Properties of FSMs: **Determinacy**

- o An FSM is deterministic if
  - Different transitions out of a state do not have overlapping guards

$$\text{guard1} \cap \text{guard2} = \emptyset$$

Is the iRobot FSM (prev. slide) *deterministic*?

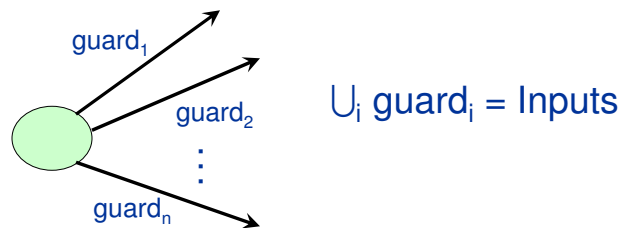

Note: A guard is a subset of Inputs

EECS 124, UC Berkeley: 16

## Properties of FSMs: **Receptiveness**

- An FSM is receptive if
  - It has a transition defined for *every input symbol* from *every state*

Is the iRobot FSM *receptive*?

EECS 124, UC Berkeley: 17

## Behavior of a FSM

How do we model the input-output behavior of an FSM?

Let

InputSeq = set of infinite sequences of input symbols

OutputSeq = set of infinite sequences of output symbols

Then, the behavior of an FSM is

*a function from InputSeq to OutputSeq*

EECS 124, UC Berkeley: 18

## Trace

A trace of a FSM is an infinite sequence of triples

$(i_0, s_0, o_0), (i_1, s_1, o_1), (i_2, s_2, o_2), \dots$

where  $\text{update}(s_j, i_j) = (s_{j+1}, o_j)$

Also written as:

$s_0 \xrightarrow{i_0 / o_0} s_1 \xrightarrow{i_1 / o_1} s_2 \xrightarrow{i_2 / o_2} s_3 \dots$

Sometimes we are only interested in the “observable” trace of the system, which includes only input & output symbols  $(i_0, o_0), (i_1, o_1), (i_2, o_2), \dots$

- Note: as above, the trace represents a single system behavior

EECS 124, UC Berkeley: 19

## Example: a Counter

Suppose the count starts with 0

Trace is

$(1, 0, 0), (0, 1, 1), (0, 1, 1), (0, 1, 1), (1, 2, 0), (1, 3, 1), \dots$

EECS 124, UC Berkeley: 20

## Example 2:

Give an example trace for the iRobot modal model on slide 15

EECS 124, UC Berkeley: 21

## Modeling the iRobot's environment

Is this model **deterministic**?

L      level=true  
NL45   level=false, 45° offset  
NL90   level=false, 90° offset

Self loops on: rotate=false

EECS 124, UC Berkeley: 22

## Non-determinism

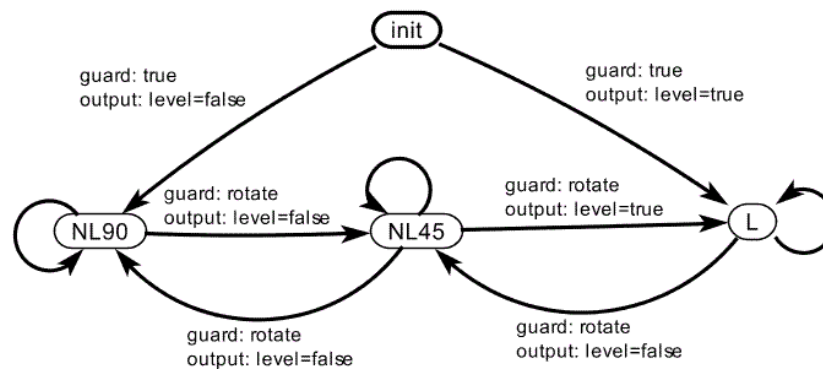

More than one transition possible on an input symbol

For the iRobot environment:  
non-determinism in transition from initial state

EECS 124, UC Berkeley: 23

## More non-determinism in iRobot's environment

Self loops on rotate=false

How will the FSM change if we want to model this:  
*Lifting up the robot at any step and placing it  
with a different orientation*

EECS 124, UC Berkeley: 24

## Uses of non-determinism

1. Modeling unknown aspects of the environment or system
  - Such as: how the environment changes the iRobot's orientation
2. Hiding detail in a *specification* of the system
  - We will see an example of this later (see notes to be posted)

Any other reasons why non-deterministic FSMs might be better than deterministic FSMs?

EECS 124, UC Berkeley: 25

## Size Matters

Non-deterministic FSMs are more compact than deterministic FSMs

- ND FSM  $\rightarrow$  D FSM: Exponential blow-up in #states in worst case

EECS 124, UC Berkeley: 26

## Non-deterministic Behavior: Tree of Computations

For a fixed input sequence:

- A deterministic system exhibits a single behavior
- A non-deterministic system exhibits a **set of behaviors**
  - visualized as a *computation tree*

Deterministic FSM behavior:

Non-deterministic FSM behavior:

EECS 124, UC Berkeley: 27

## Non-determinism: Formal Definition

A non-deterministic state machine is a tuple:

(States, Inputs, Outputs, possibleUpdates, initialStates)

where

States = set of states/modes of the system

Inputs = set of input symbols

Outputs = set of output symbols

**possibleUpdates: States  $\times$  Inputs  $\rightarrow$   $2^{\text{States} \times \text{Outputs}}$**

- also termed as “transition relation”

initialStates = the starting states/modes of the system

EECS 124, UC Berkeley: 28

## Related points

What does receptiveness mean for non-deterministic state machines?

Non-deterministic  $\neq$  Probabilistic

EECS 124, UC Berkeley: 29

## Representing a state machine

1. Pictorial notation
2. Table representing transition relation
3. Functional notation

When would you use each representation?

EECS 124, UC Berkeley: 30
